Comments	on a	paper	entitled	The	Calculation	of	20A16£	Helicobter
Perform	mce"				25X1A9a			

- 1. The author makes no mention of the fact that for the past ten years, at least, the intelligence community has concentrated considerable effort upon the analysis certain 25X1X1 principles of t has been possible to estimate aircraft performance. ACIC has been very active in such analysis, and has frequently called upon the U.S. aircraft industry for 25X1X1 Mig-15, used in connection with guidance. From other available intelligence, ATIC estimated performance which when checked out with the actual aircraft some years later proved to be extremely accurate. While bomber and fighter aircraft have taken priority over other types of aircraft in this kind of analysis, other types including belicopters and transports have also been amlysed using the same techniques.
- 2. I have no criticism of the author's method of estimating helicopter performance, because once such assumptions as, horse-power rating, blade tip speeds, rotor disc area and gross weight of aircraft have been resolved methods, the actual performance calculation is fairly routine. However, I suggest that the paper be coordinated with the people in ATIC who have estimated Soviet helicopter performances by this method in the past.
- 3. 25 Me left with the impression that the author has put forth an original idea for the writer has treated two subjects which, in my opinion, should be treated in separate papers. I suggest papers entitled as follows: first; "Intelligence Techniques Utilized to Determine Parameters for Estimating Helicopter Performance", and second; "A Method for Calculation of Helicopter Performance." The first paper would deal with the intelligence problems involved only, while the second would deal only with the calculation of helicopter performance whether US or USSR.
